#### MISCELLANEOUS NOTES.

### No. I.—TIGER (FELIS TIGRIS) KILLING AND EATING ITS YOUNG.

I have often wondered how it is that I have seldom found more than two and never more than three cubs with a tigress although on two occasions when I have been so unfortunate as to shoot a pregnant tigress I have found as many as five unborn cubs inside her. Until a short time ago I accounted for this with the theory that possibly the tigress eats some of her cubs soon after they are born—a habit not unknown with other animals I believe.

Recently however I have come to change my views.

On May 20th I had joined camp with Mr. Symes who was shooting in this district. A tiger, a tigress and two cubs were known to be about and the previous night and in the very early morning the rather unusual roar of a tiger was heard for some time. In the direction of the roars a prepared kill had been taken by a tiger and later about a mile beyond this kill a natural kill of a sambur by a tigress was found. We decided to beat over the artificial kill first. The beat was blank the tiger having gone out of the beat beforehand towards the other kill. The beaters however found two dead half-grown tiger cubs in the beat which had clearly died in the evening before.

We examined these dead cubs and found that they had been killed by a male tiger and both of them partially eaten at the haunch. They had both been killed in the same place but one of them had been dragged some hundred and fifty yards from its dead companion. It was interesting to see that the cubs besides being rather severely bitten in the throat had been much clawed in the arm pits, in fact sufficiently so to alone cause their death.

Local natives, who certainly ought to know something about tigers, say that a male tiger will always kill cubs if he comes across them, and after this interesting experience one can well believe it. In this particular case the tigress had probably left her cubs early in the evening and killed the sambur. While she was busy with this the tiger probably came across the cubs on his way down to the water where the kill was. After disposing of the cubs he must have gone for a drink and killed the bait tied up for him. The roars we heard were probably those of the distressed mother and perhaps it was well that she was not in the beat.

Mr. Symes also corroborates the facts of this story.

BILASPUR, C. P., 6th July 1912.

[In Vol. VII. of our Journal (1892), page 253, we published a note by Colonel Scott of Palanpur, on "Tigers eating their young."—EDS.]

### No. II.—CANNIBALISM AMONG PANTHERS (FELIS PARDUS).

About a week ago I had three panthers, said to be a large male, a female and a small male, marked down in some dense thorn jungle chiefly candelabra cactus and babul not many miles from Veraval.

The jungle was far too close to beat, so I tied up a live goat and sat over it in a machan about 6 P.M. A medium sized male panther came at 6-30 and I hit him hard with a 500 express bullet. He turned and jumped back into cover, and, on examining the spot, I found a piece of lung on a stone, and a thick trail of light-coloured frothy blood leading into the thick thorn jungle. I knew then that he was hit through the lungs and could not go far, so I decided, as the cover was so thick, to leave him till next morning. In the morning I found him lying about 50 yards away the other side of a thick clump of cactus through which he had dragged himself. Imagine my disgust to find that he had been more than half eaten and the skin of course ruined. The head, chest and forelegs, hindlegs, tail and part of the rump were untouched, the rest of him was eaten, the ribs bitten off close to the spine.

All round were the footmarks of the female and the small male, so there is no doubt that they had made a square meal of their dead relation. There were no signs of jackals or hyenas. The dead panther had very large pads, and this accounted for his being described as a large male though as a fact he was only a medium size.

I remember reading of a similar case in a previous note in our Journal, but I believe such cases to be sufficiently rare to make this one worth noting.

J. R. CARTER, Major,
Bombay Political Department.

CAMP VERAVAL, 7th June 1912.

[Cases of this kind have already been recorded both amongst tigers and panthers in Vol VI. and XVII of this Journal.—Eds.]

# No. III.—NUMBER OF A PANTHER'S (FELIS PARDUS) CAUDAL VERTEBRÆ.

In my notes in the last number of the Journal on Mr. Hick's book "Forty years among the wild animals of India" I referred to his statement that two species of panther are distinguishable, among other differences, by the 'fact' that the large 'species' has only 22 vertebre in the tail while

the smaller has 28. It is of interest therefore to record that in April last in the Mahi Kantha Agency I shot a female panther measuring 6 feet 2 inches (including tail of 2 feet 7 inches) the number of whose caudal vertebræ on careful examination proved to be 24. As a single instance is insufficient to dissipate what I believe to be a myth, it may be hoped that others will be reported by members of the Society.

PALANPUR,

23rd July 1912.

#### No. IV.—NOTES ON MARTENS IN KASHMIR.

Toiling up a moraine one afternoon with a friend at Sonemurg and when at an elevation of about 11,000' he suddenly gave a low whistle from behind me and beckoned me to his side. There not five yards from us appearing from beneath a rock was a fine example of The Beech Marten (Martes foina). The animal did not appear much disquieted by our presence, continuing to sniff and gaze around, till one of us made a slight movement when it withdrew beneath the rocks. We waited some time for its reappearance but it evidently decided to stay at home, or had slipped away by a hidden passage beneath the moraine.

Imagining that we had found the entrance to its lair my friend a few days later set up a camera and waited on the chance of securing a photo, but there was no further sign of the Marten, only a few mouse hares appeared from beneath the same rocks and played about. Later on I went up to try my luck with a gun and to endeavour to secure the Marten as a specimen. But I waited in vain and had to contend myself with a mouse hare which came out at the same spot as the marten had. The presence of these mouse hares rather upset the theory that we had discovered the Marten's lair, and we came to the conclusion that, when we saw the latter, it was hunting, and had been prospecting the mouse hare burrows under the rocks from beneath which we saw it emerge. It is hardly likely that a Beech Marten and mouse hares would live amicably side by side. The biblical "Lion and lamb" miracle would be quite eclipsed by such a state of affairs.

In the same locality, the Indian Marten (M. flavigula) frequented the forests just below.

G. C. SHORTRIDGE.

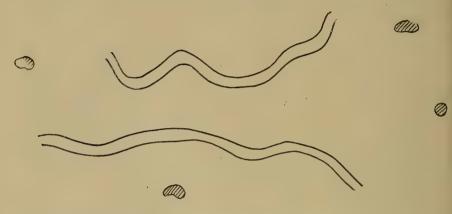

etc.)

August, 1912.

<sup>\*</sup> Mr. Shortridge's notes were submitted to Mr. Wroughton who has added a few remarks in brackets under his initials R. C. W.—EDS.

#### No. VI.—THE HABITS OF VOLES.

Where voles of the genus *Microtus* are common in Kashmir and Himalayas, a curious phenomenon is revealed, on the melting of the snow, which covers their burrows in winter, in the long tortuous ridges of clay left lying on the surface of the ground. These ridges, often some yards in length, are *solid* throughout, more or less cylindrical, and from 2 to 3 inches in diameter in section. As often as not they are unconnected at their extremities with the entrance holes of the voles. The rough sketch below will perhaps explain my meaning better than the description, viz:—

A friend who had also noticed and taken an interest in these curious ridges informed me that he had once found them in the melting snow on a hillside, running through the snow and not in contact with the ground though close above it. This discovery shed some light on what was a perplexing puzzle, and led to the formation in my mind of the following vague theory of their origin, one which however does not altogether satisfy me.

If any of our readers can enlighten me with the true and scientific explanation I shall feel indebted to him or them.

I imagine then that, when their burrows are buried deep in snow, these voles abandon their usual habits of burrowing connecting passages underground (such passages being likely to collapse when the snow melts, and thus to lead to flooding of burrows), and construct instead passages along the surface of the ground and through the snow. But, in order that these passages may be kept dry and warm, earth is pushed up into the snow to form a roof above and possibly walls along the same, the earth for this purpose being excavated and brought from the holes, as no trench is ever apparent under the ridges in question or connecting the holes. When the snow melts on a slope these ridges can rarely, owing to force of gravity, be deposited on the ground vertically below the position they occupied in the snow, and must therefore often come to rest some little way down hill.

This explains their seeming lack of connection with the holes when found on dry ground. On deposition also the walls, if any, would tend to collapse and quickly assimilate with the surrounding soil.

Whatever the explanation of these mysterious ridges, however, they, at all events, hear silent witness to the activity of these little rodents when their homes are buried deep in winter snows and show that hibernation is not entirely spent in sleep.

KASHMIR, 1912.

#### No. VII.—THE INDIAN BUFFALO (BUBALUS BUBALIS).

In the Bellary Gazetteer published in 1904, attention is drawn to the fact that "Many of the buffaloes in the district are peculiar in having a white patch between their horns." I have noticed that this is also of frequent occurrence in the North Kanara, Mysore and Dharwar districts, the white varying in size from a small patch, to the whole forehead; more rarely extending over the face. Another curious form not uncommonly observed is that in which the eyes are of a clear, almost China-blue instead of the usual dark brown.

In Blanford's "Fauna of British India" the only mention of any colour variety of the domesticated buffalo is "that the legs are occasionally white to the same height as in the Gaur," while the fact is noted that few of any animals have charged less in captivity than the Indian buffalo.

It would be interesting to know if this variety with the white forehead is peculiar to the south, or whether it is found throughout India.

Any one who has been in Java may have noticed the extremely large number of entirely albino buffaloes there, quite 20 per cent. of those on the island.

The Banting (Bibos sondaicus) is also very successfully domesticated in Java and Bali where it is indigenous.

G. C. SHORTRIDGE.

CAMP, BELLARY, August 1912.

[Both the variations mentioned by Mr. Shortridge are to be seen amongst the dairy buffaloes in Bombay which come chiefly, we believe, from Gujarat, Kathiawar and the Punjab.—Eds.]

## No. VIII.—TSINE (BIBOS SONDAICUS) CONSORTING WITH TAME CATTLE.

I was greatly interested in Mr. Hauxwell's note in the Journal published in July of a bull Tsine (*Bibos sondaicus*) consorting with tame cattle. To quote Mr. Hauxwell, "it is not an old bull, and it is strange why it should have taken to this solitary life. Can it be that it has been driven out or

the herd by an older and stronger bull, and so forced to come to the village cattle for companionship?"

I make no doubt that this is exactly what has occurred. I have known of three similar cases, two of Tsine consorting with tame cattle, and one of a Gaur which had attached itself to a herd of tame Mithan (Bibos frontalis). All three were young bulls-I have also heard of an old bull Tsine which was supposed to frequent cultivation in pursuit of tame cattle; but as my informant was a Burman it is possible that he may have been deceived by the size of animal into thinking it an old bull. An old bull Tsine shot by me was said to be this very beast, but I always had my doubts on the subject. His tracks were found some miles from the nearest cultivation and he was killed in dense Bamboo jungle. Still he may have consorted with tame cattle from time to time and the fact that he was well past his prime lends colour to the supposition. As all sportsmen know who have hunted Gaur and Tsine frequently, it is by no means an uncommon occurrence to come across quite young bulls leading a solitary existence, and the only explanation that presents itself is that they have been driven from the herd by the master bull. One would naturally expect, therefore, that when Tsine are found consorting with tame cattle they would be young bulls, or very occasionally old bulls past their prime. The sexual instinct would naturally be stronger in young bulls than in animals past their prime, and the former would also be less shy and wary than the old stagers. At the same time it is conceivable that in the case of very old bulls driven from the herd by stronger rivals, the sexual instinct would in some cases assert itself and the animal, debarred from consorting with its own kind, would occasionally take refuge in an artificial existence rather than become a recluse for good. Such cases, if they occur at all, must be of rare occurrence, and it would be interesting to have authenticated data on the subject. I do not know of any case of a bull in its prime-whether Gaur or Tsine-consorting with tame herds of Mithan or cattle, and it would seem to be extremely unlikely that any such could occur. My own theory is that when such animals take to a solitary existence they do so from choice, and merely for the time being. It was once my good fortune to shoot an erstwhile solitary bull Tsine while with a herd which he had joined on the day he was killed. This beast was a bull in his prime with a very fine head, showing no signs of advanced age. He had merely joined a herd when it suited him to do so. It may be asked why such an animal finding itself near a herd of village cattle should not join them as a younger beast occasionally does. The obvious reply is that the younger animal having been driven from a herd of his own kind is faced with two alternatives—either to remain solitary until old enough to take possession of a herd or to consort from time to time with tame cattle. The older beast on the other hand can appreciate a herd whenever inclined to do so;

for even if driven from his own herd—an unlikely supposition—he is sufficiently powerful to find other herds in which he can hold undisputed away. But I would not be held to dogmatise on a subject of which we know very little. I state my theory for what it may be worth, in the hope that some observer with more knowledge of the subject than I can lay claim to will be able to throw more light on this very interesting question. While no one can account for the vagaries of individuals even in the animal world, it will, I think, be admitted as a general rule that for wild animals to consort with tame is an unnatural state forced on them by circumstances beyond their control, and that no animal having access to its kind is at all likely to seek an artificial existance even for a short period.

MALAKAND, 20th August 1912.

G. P. EVANS, MAJOR, XIX Punjabis.

# No. IX.—HABITS OF THE KASHMIR STAG (CERVUS KASHMIRIENSIS) IN SUMMER.

The comparatively high altitudes to which the Kashmir Stag ascends in summer has probably attracted little attention, interest in this animal being, as a rule, confined to the shooting season when it descends, and keeps mainly to the forest levels. This year I frequently saw 'Barasing' (so called) and their numerous tracks on a hill top, 14,000', and on one occasion observed a herd of about 16 hinds at 14,000' and still climbing by a track which would take them to the water shed 15,000' and over, and for which I have little doubt they were making. These high ascents, far above forest levels, are made in the mornings, and are generally for the purpose, besides grazing, of indulging in a midday siesta at some elevated spot where fancied security from enemies may be obtained.

The unwariness of a big stag met with one day afforded me what must be a rare, if not unique, experience. On a hillside at 13,500' the sudden appearance of what, at first sight, looked like a great caribou head, over a snow field above me caused me considerable astonishment. But realizing that caribous do not exist in the Himalayas, and that it was a big stag in velvet, I had to deal with, I stood and watched, and saw the 'head' slowly sink behind the snow again. Feeling sure that the owner thereof had settled down to rest I decided to stalk him. The only route lay to windward and a fresh breeze was blowing across the hill. Notwithstanding I managed to reach unobserved and unwinded a small mound behind which I suspected he was lying. Creeping up and peeping cautiously over, there, sure enough, lay the great beast—a true 'monarch of the glen' fast asleep and only 16 yards (paced) away. Luckily my terrier, who was

behind me, did not scent or spot the sleeping animal, and I was able to survey him at leisure. Though he lay with head towards me and I was quite conspicuous, taking little trouble to conceal myself, he never winked an eye, only his ears flapped lazily keeping off the flies. The head was a fine one (12 pointer) but thick in velvet. The coat was patchy and evidently in process of being shed. I gazed my fill, then dropping quietly behind cover again, left him to his siesta and passed on up the hill. As luck would have it my camera was not with me that day and I have since often regretted the unique snapshot lost. From a coign of vantage, some 800 yards beyond and above, not a movement of the stag could escape me so I sat and munched my sandwiches and enjoyed the panorama of snowy peaks and glaciers spread before me.

For 2 hours or more he slept peacefully. Then, rising, shook himself, sauntered across the snow, and proceeded to drink at a puddle left by the melting snow, after which he began to drop slowly down hill, on the steep side, browsing the while. Wishing to have a last look at him on my way down I made for the spot where he had disappeared from view and peered over.

There he still stood, some 80 yards below, browsing quietly. I let him see me but he evinced little sign of fear, merely dropping a few feet lower, and resuming his browsing. But for my terrier which, this time, spotted him and gave him chase, I could have approached him much closer. Seeing the terrier he rattled down hill and out of view, leaving a void in the picturesque landscape.

When descending a hill these stags look awkward and clumsy compared with the graceful bounding movements of Markhor or Ibex.

Some days later a further curious experience with Kashmir Stag befell me on this same hill. Climbing it with a brother officer we had a cooly with us carrying our paraphernalia. When some way up I asked the latter if he had ever been on this hill before and if he knew that "Barasing" lived on top. He replied that he had not, and expressed a desire to see a "Hangul." This I undertook to promise to show him. Within 5 minutes of this conversation, appearing slowly over a ridge to our left, we saw the antlers of a big Barasing, then the whole animal standing on the sky line. Following him came another, then another, and still others, until there were five grand stags, all apparently good shootable heads, standing in full view and barely 400 yards away! No one was more astonished than I, for although feeling pretty confident of meeting with a stag that day, I was not prepared for the splendid fulfilment of my promise in the vision we had just seen. For some days after this I believe I bore the reputation of being a "Jadu-gar."

Kashmir, August 1912.

### No. X.—ABNORMAL TYPE (?) OF EGGS OF THE LITTLE FORKTAIL (MICROCICHLA SCOULERI, Vigors).

On the 12th May last, I found a nest of this species placed in the niche of a rock by the side of a large waterfall in the neighbourhood of Simla. The position of the nest was betrayed by one of the birds, which hurriedly left the spot on my approach. On examining the nest I found that it was practically completed, and was ready for the birds to lay in. Allowing a few days to elapse I sent one of my hunters to bring away the eggs, if any, and also the nest. He carried out my instructions, but, on examining the eggs, which were quite fresh and three in number, I was much astonished to find that they were pure spotless white. I immediately questioned my man as to the identity of the bird, which he knows well. He firmly maintained that the eggs in question belonged to this Forktail, that he had distinctly seen it leave the nest on his approach, and that when he removed the eggs they were quite warm. I have no reason whatever to doubt the man's statements, for I have always found him truthful, and in this instance there was no particular reason for him to deceive me; but nevertheless I still feel rather disturbed about the colouration of these eggs. Had I for a moment foreseen this contingency, I should of course have spared no pains to put the identity of the bird beyond doubt. As things stand now, there is doubt but doubt which can be dispelled by the experiences of other Ornithologists.

I should like to know whether this Forktail, like some other birds, for example, *Dicrurus ater*, lays eggs of two different types: one, pale dingy pink, spotted and speckled with reddish brown, and the other pure spotless white?

The eggs from this nest are, as already stated, pure spotless white, and they have a distinct gloss. In shape they are somewhat elongated ovals, slightly pointed towards the small end. Their measurements compare as follows with those of the normal type:—

Abnormal type (?) of eggs.

(1)  $\cdot 81'' \times \cdot 58''$ (2)  $\cdot 82'' \times \cdot 58''$ (3)  $\cdot 85'' \times \cdot 6''$ Normal type of eggs.

Average measurements of 11 eggs  $= \cdot 79'' \times \cdot 57''$ 

I may add that there is no doubt whatever about the nest. It was of the usual Forktail type—a small cup, composed externally of moss, and lined with a little dry grass, and a few dead and skeleton leaves.

Since the publication of my notes about this species at pages 257—261 of Vol. XXI of the Journal, I have found the following nests in addition to the one mentioned above:—

(i) Keonthal State, 1st May: elevation 5,000 feet; nest with three young, just hatched.

- (ii) Keonthal State, 21st May; elevation 5,000 feet; 3 hard set eggs (normal type).
- (iii) Ditto. 21st May; elevation 5,000 feet; two young, full fledged.

P. T. L. DODSWORTH, F.Z.S., M.B.O.U.

SIMLA, S. W., 29th August 1912.

# No. XI.—NESTING OF THE WESTERN BLUE ROCK THRUSH (PETROPHILA CYANUS, Linn) IN THE NEIGHBOURHOOD OF SIMLA, N.-W. HIMALAYAS.

After several years of fruitless search, I have at last succeeded in finding the nests of this species, which is a tolerably common summer visitant to these N.-W. Himalayan ranges, arriving in April, and leaving about the beginning or middle of September.

In the neighbourdhood of Simla, it breeds at elevations of 6,000-7,200 feet, on bare rocky hills, during May and June. The nests are shallow saucers, in some cases mere pads, adapted to the shape of the cavities in which they are placed, and are composed externally of dry grass, lined with rootlets. The diameter of the egg-cavity does not exceed 4", and its depth is about  $1\frac{1}{2}$ ". The external diameter varies from 5 to 6", and the height is about  $2\frac{1}{2}$  or 3". The nests are placed sometimes in low stone walls occasionally under boulders, but more frequently in fissures or crevices of large rocks.

The number of eggs is usually four, and their colouration is exactly as described by Dresser in his "Manual of Palaearctic Birds", page 23. The "speckled" eggs seem to be the commoner type.

The average of 12 specimens measured was  $1.01'' \times .75''$ .

Between the dates 18th May and 20th June, I found, in addition to the eggs mentioned above, no less than eight nests containing young ones. Five of these nests had three young each, and two, four young each: the exact number of young in the eighth nest could not be satisfactorily ascertained, as the latter was placed very far back in the fissure of a large rock.

The nests of this Thrush, especially when they contain eggs, are most difficult to find, as the old birds are very cautious and wary in their movements, and it is only by patient and laborious watching that one can hope to be successful with them. The cock bird, though he helps in feeding the young, and is always much in evidence when the eggs are hatched, keeps far away from the scene when building operations are in progress. The hen alone carries the materials, and if she catches sight of one, or suspects that she is being observed, will sit on a rock, with the grass in her mouth, for whole hours at a time, rather than give away the show.

When there are eggs in the nest the hen bird sits very close, and on two occasions I have caught her on the nest. So far as my experiences go, I do not think that the cock takes any part in the hatching of the eggs.

P. T. L. DODSWORTH, F.Z.S., M.B.O.U.

SIMLA, S. W., 29th August 1912.

## No. XII.—THE HIMALAYAN GREENFINCH (HYPACANTHIS SPINOIDES).

In Mr. P. T. L. Dodsworth's interesting note on Hypacanthis spinoides (The Himalayan Greenfinch) in Vol. XXI, No. 3, p. 1076 of this Journal, he gives the distribution of this species as follows :-- "Along the Himalayas at elevations 6,000-10,000 and perhaps even higher from the south side of the Pir Panjal Pass in Kashmir (Brooks) to Sikkim (Blanford) also recorded from Manipur (Godwin Austen). During the cold weather these birds move to tower elevation, and the N.-W. Himalayan ones at all events are found in the Duns and plains (Bijmor to Pilibhit) at the foot of the mountains (Osmaston). In quoting this as the distribution Mr. Dodsworth has apparently overlooked various publications in this Journal from the pens of Colonel Rattray, Captain C. H. T. Whitehead and others which add considerably to our knowledge in this respect and shew that the range of The Himalayan Greenfinch extends very much further to the North-West. For example it is common in the Murree Hills and Hazara. It occurs in the N.-W. F. P. (Samina), and not improbably breeds in the Kurram Valley. I may add also that in parts of the Peshawar Valley it is a common winter migrant, being freely snared there for the Peshawar bazaars, where it is a favourite cage bird with the Pathans. With regard to Kashmir its range extends well north of the Pir Panjal and the Vale of Kashmir itself, in the Liddar and Sind Valleys, it breeds commonly from 7,000 to 9,000 ft.

H. A. F. MAGRATH, LT.-Col.

Kashmir, August 1912.

#### No. XIII.—EARLY ARRIVAL OF GREY WAGTAIL.

I am sending you a specimen of what I think is the Grey Wagtail (Motacilla melanope) shot near here on the 22nd August, by a stream in the midst of dense jungle. Chikalda is 125 miles south of Sehore as the crow flies; but Capt. Whitehead, in his article which appeared on page 153 of Vol. XXI of the Journal, notes its earliest appearance at that place as the 20th September. Considering how late the rains broke here, not until the 10th July, and that it breeds in Kashmir above 6,000 ft. and in Afghanistan in May and June (dates on p. 294 of Vol. II, F. B. I.) This must be distinctly an early bird.

Will you kindly verify my identification of the specimen which is unfortunately in a somewhat shattered condition?

J. DONALD, I.F.S.

CHIKALDA, BERAR, 22nd August 1912.

[The bird is as Mr. Donald suggested a Grey Wagtail M. melanope.—EDS.]

### No. XIV.—EGGS OF THE LARGE HAWK-CUCKOO (HIEROCOCCYX SPARVERIOIDES).

In his "Indian Parasitic Cuckoos" Mr. E. C. Stuart Baker reproduces an article of his printed in the Journal of the Bombay Natural History Society in 1906. The article shows that at the time of writing, the oology of this cuckoo was not so thoroughly known as not to require further investigation. Colonel Rattray was then the only person who had obtained undoubted eggs of the bird, and though these were blue Mr. Stuart Baker hinted at the possibility of there being also a chocolate coloured variety.

For many years my brother Mr. B. B. Osmaston has tried to obtain eggs of this cuckoo from the Himalayan region round about Naini Tal where at suitable elevations it is no uncommon bird. During the rains of 1911, he found a nest of the Red-headed Laughing-Thrush (*Trochalopterum erythrocephalum*) close to Naini Tal and it contained two Laughing-Thrush's eggs. Intending to rear the young birds he sent his chaprassy a few weeks later to fetch them. The chaprassy returned with a young cuckoo, the sole occupant of the nest, and the cuckoo proved to be a young one of *H. sparverioides*.

We now knew that this cuckoo laid her eggs in the nest of this bird, and we decided to thoroughly search the same place again this year for eggs. The hill overlooking Naini Tal rises to a height of 8,600 feet, and for the last 1,000 feet the vegetation is chiefly "Karshu" oak mixed with shrubs of various species. There are scarcely any birds breeding here during the rains excepting the Red-headed Laughing-Thrush (Trochalopterum erythrocephalum) and Himalayan Streaked Laughing-Thrush (Trochalopterum lineatum) and of these the former is by far the commoner. In the beginning of June my brother visited the place and found the Large Hawk-Cuckoo calling incessantly and in considerable numbers, but the Redheaded Laughing-Thrushes had hardly commenced nesting. At the beginning of July the cuckoos were still continually to be heard and the Laughing-Thrushes were nesting in earnest.

On 7th July I found a nest of *T. erythrocephalum* containing two fresh Laughing-Thrush's eggs and one fresh cuckoo's egg. The nest was about six feet from the ground in a dense holly bush. When I took the eggs a cuckoo (*H. sparverioides*) was calling lustily only fifty yards away.

On 18th July I found another nest of T. erythrocephalum containing one

fresh cuckoo's egg. The nest was placed about 8 feet from the ground in a small Deodar. There is some mystery about this nest as it contained no Laughing-Thrush's eggs nor were the parents lurking round as they usually do. In fact there had evidently been some tragedy recently enacted for the nest contained besides the cuckoo's egg, a small piece of fresh meat with a little skin and a few bedragled feathers adhering to it. The nest, however, was not disturbed. When I found the nest a cuckoo was calling persistently only 100 yards away.

On 28th July I found another nest of the same Laughing-Thrush about eight feet from the ground in a young oak tree. It contained one Laughing-Thrush's and one cuckoo's eggs, both quite fresh. This time I did not hear the cuckoo calling as on previous occasions.

These three nests containing cuckoo's eggs were all found within a quarter of a mile of one another, and on the many occasions on which I hunted the locality I never failed to hear the cuckoo calling close round, yet never heard the call of any other cuckoo. The elevation was about 8,200 ft. Though there is no absolute proof of their identity there is little room for doubt, considering also that they agree with the authenticated eggs obtained by Colonel Rattray.

All three eggs are of the same colour and texture. They are pale greenish-blue (almost exactly the same blue as the ground colour of the Laughing-Thrush's eggs) and distinctly glossy. They are also traced by distant corrugations and minute raised dots. Their shape is a narrow oval compressed at the smaller end in two of the specimens, but not in the third. The dimensions of the eggs are as follows:—

```
Egg taken on 7th July 1912 ... 1·18"× 81"

" " 18th July 1912 ... 1·10"× 81"

" " 28th July 1912 ... 1·11"× 84"
```

The eggs of the Laughing-Thrush are ordinarily spotted round the larger end though occasionally unspotted eggs occur, but even in these rare cases the cuckoo's eggs may be at once recognised by their glossiness, those of the Laughing-Thrush being entirely without gloss.

NAINI TAL, 21st August 1912.

A. E. OSMASTON.

### No. XV.—QUESTION WHETHER GYPS FULVUS, Gmelin, THE GRIFFON, OCCURS IN THE HIMALAYAN DISTRICTS OF THE PUNJAB.

Assuming that the Gyps fulvescens of Hume is identical with the Gyps fulvus of Gmelin, the common Griffon of Europe, I should feel much obliged if some Ornithologist would kindly let me know whether he has observed this bird in the Himalayan districts of the Punjab, and, if so, at wha places?

Strachey records \* it from Kumaon, and Blanford gives (Fauna, B. I. (Aves), iii, p. 320) its range in the *Himalayas* as extending east as far as Nepal and Sikkim, but I have been unable to trace all the data on which the latter statement was founded.

The common species in the neighbourhood of Simla is the Himalayan Griffon, Gyps himalayensis, Hume. And this is the Vulture, not Gyps fulvus that Colonel C. H. T. Marshall mentions (Ibis, October 1884, p. 405) in his list of Chamba birds.

Hume spoke (Rough Notes, p. 21) of the Griffon—his Gyps fulvescens—as the "Vulture of the desert," and it seems only reasonable to conclude that if it had occurred in the N. W. Himalayas, he would surely have mentioned the fact.

1 see that Colonel Ward includes (J.B.N. H. S. Vol. XVII, p. 728) Gyps fulvus in his birds of Kashmir, where, he says, it is resident in many districts, but on the other hand it is significant that Davidson never saw it there (Ibis, January 1898), and all the Vultures procured by Dr. Abbott (Proc. U. S. N. M. Vol. XVIII, p. 453, and Vol. XXII, p. 210) in that country turned out to be Himalayan Griffons—a totally different species.

P. T. L. DODSWORTH, F.Z.S., M.B.O.U.

SIMLA, S. W., 27th May 1912.

[In 1869 Hume described Gyps fulvescens and on account of the knowledge of its distribution then wrote of it "as the Vulture of the desert." Since, however, this vulture has been recorded from Nepal and still later under the name of Gyps fulvus by Colonel Rattray from Thull and Captain Whitehead from the Kurram Valley. Though Dr. Blandford treated fulvescens as a synonym of fulvus, Dr Sharpe both in his catalogue and hand list considered them distinct giving the distribution of fulvus as "S and C Europe, N. Africa and Sudan," and that of fulvescens as "Afghanistan, N. India"—EDS.]

#### No. XVI.-A KITE'S LARDER.

With reference to Mr. Remington's enquiry in the last issue of the Journal, I do not think it is usual for this species (Milvus govinda) to make "larders." During a course of observations extending over several years, I have only once come across a "larder." It was in Calcutta where, on a certain tree, a pair of these Kites have bred for several years in succession. From my Office window the nest was not distant more than 10 feet, and I hal ample opportunities of closely observing the owners. I noticed that the Kites frequently brought dead rats, bones, pieces of meat, and ate them on the edge of the nest, leaving the scraps behind to

<sup>\*</sup> Is it possible he confused this bird with Gyps himalayensis, Hume?

be devoured at leisure. Both the old birds resorted to this "larder" at frequent intervals during the course of the day, and for many months after the young had left the nest.

In connection with the breeding of this species, I may mention that I have frequently found lumps of clay and small stones in their nests when the latter contained eggs (see also Jesse in "Ibis," January 1903, p. 75), but have never yet been able to make out what purpose this rubbish serves. I daresay other Ornithologists have had similar experiences, and it would be interesting to know what explanations, if any, have been advanced in regard to this curious practice indulged in by these Kites.

SIMLA, S. W., 29th August 1912.

# No. XVII.—TAMENESS OF GREAT INDIAN BUSTARD $(EUPODOTIS\ EDWARDSI).$

With regard to the recent articles on Bustard in your Journal, readers may be interested in hearing that, in spite of the extreme wariness of the Great Bustard, on the 15th of May this year, I came upon a pair of these birds wading at the edge of a large pand and drinking. The pond itself is about half a mile from a town of considerable size and there were at the time a group of dhobies washing clothes on the opposite side of the pond within 200 yards of the Great Bustard. I myself walked to a point just opposite them, and about 90 yards distant from them, so there can be no mistake about their identity. I enquired whether any had been seen before in the locality and was informed that they had not. It would also appear that these particular birds were in the practice of coming here to drink, for a friend of mine who happened to visit the pond some three days later also says he saw them. I do not suppose for a moment that it is an unknown characteristic of the Great Bustard that he should come to drink at ponds, but I am surprised that such a retiring bird as he should come to drink at a popular dhobies' ghat.

FEROZEPORE, PUNJAB, 4th August 1912.

#### No. XVIII.—BUSTARD IN KATHIAWAR.

In ordinary years during my district touring in Sorath Prant I have occasionally come across a solitary Great Indian Bustard (*Eupodotis edwardsi*) sometimes two or three together, but they are by no means

common. This year owing to the failure of rain in other places I suppose these birds have been seen in large numbers throughout the Prant. In all I have seen over fifty close to my headquarters alone. In one morning I came across two distinct groups of 9 and 10 together. At the time of the bajri harvest they could be easily bagged with a shot gun, being feeding so busily as to be quite off their guard, and I once got two fine cock birds 18 and 20 lbs. in weight, left and right. After the crops were cut they could only be bagged with a rifle. One male bird of 16 lbs., I had shot with a 310 rifle and on picking him up by the legs to feel his weight a long red thing dropped from his mouth. On examining it closely I found it to be the partially digested body of a snake about 2 ft. long. In the stomach of the same bird I found another snake, "a phoorsa," evidently recently swallowed, and two stones measuring  $1\frac{1}{4}$  inches by 1 inch. I have got the snakes and stones in spirits and will send them to you on the first opportunity. As the hot weather advanced the Bustard disappeared and I have not seen one since early in April.

> J. R. CARTER, Major, Bombay Political Department.

CAMP VERAVAL, 7th June 1912.

### No. XIX.—THE GREAT INDIAN BUSTARD (EUPODOTIS EDWARDSI).

During a shoot in February 1906 in the Bikaner State near Bhatinda, with a party of four guns, Mr. R. Sale Bruise, Punjab Police of Karnal, shot a male bustard. The neck of the bird was pure white, its length from tip of wing to tip of wing was exactly 98 inches and the weight 24lbs. The food bag contained, whole ears of barley; some (blister?) beetles, and a snake about 9 inches long.

Two females were also shot close by, but they weighed only 8 and 9 lbs. They had also been feeding on barley and beetles, but had been unfortunate in their hunt for reptiles.

A. B. AITKEN.

QUETTA, 20th August 1912.

[We are glad to welcome this note from Mr. A. B. Aitken, the son of the late Mr. E. H. Aitken, one of the founders of this Society.—EDS.]

### No. XX.—THE MASKED BOOBY (SULA CYANOPS) IN BOMBAY HARBOUR.

Through the kindness of Mr. E. R. H. Jackson of the Bombay Port Trust, the Society has received a fine specimen of the Masked Booby, which was captured in an exhausted condition on a dredger near the new

dock works. In 1909 a similar specimen, also captured in the harbour was presented by Mr. Jackson and there is another specimen in the Society's collection labelled "Bombay Coast, 25-7-02". Mr. W. F. Sinclair writing of this bird in an early number of the Society's Journal says that "It is not uncommon for these birds to be brought up here (Alibag) by south-westerly gales and be caught by hand."

According to the catalogue of birds in the British Museum this bird is found in the tropical seas throughout the world, but when the catalogue was published there were in the collection only two skins from north of the equator, one from Tenasserim and the other from the Mekran Coast. In the Handlist of birds, however, the distribution is given as "S. Tropical Seas."

#### No. XXI.—BAIKAL OR CLUCKING TEAL (NETTIUM FORMOSUM).

The S. S. "Empire" of the Eastern & Australian Line on her homeward voyage from Japan to Australia in January 1912 had on board a consignment of about 300 Baikal or Clucking Teal in cages. The cages were kept on the bridge deck out of the way of the passengers, where they could not be seen. The passengers in the smoking saloon of the upper deck were always aware of the continual clucking noise that the teal made. The noise was very similar to that made by a clucking hen. In fact all the passengers were under the impression that the Captain, for some reason known only to himself, had a large stock of clucking hens on the bridge deck. One passenger, who was told that the noise proceeded from ducks, would not believe till he saw and heard with his own eyes and ears. The purser was unable to give any information beyond the fact that the teal had been shipped in Shanghai and were consigned to Port Darwin, and that a similar consignment was carried on every voyage.

QUETTA, 20th August 1912.

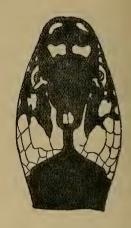

No. XXII.—IS LYCODON GAMMIEI (Blandford) AN ABERRANT SPECIMEN OF LYCODON FASCIATUS (Anderson)?

In Vol. XXI of the Journal (Part I, page 279) Major Wall compared my specimen of *L. fasciatus* obtained in the Eastern Himalayas with the type of *L. gammiei* which is in the Indian Museum.

Regarding the point of the loreal shield, I must admit that it is pointed, to some extent, posteriorly and not anteriorly as stated, the third labial and the præocular intervening between it and the eye.

I figure the exact condition of this shield and also a drawing of the markings on the head. The dark portions are deep black and the rest yellowish green. The illustration is about twice the natural size.

NAGPUR, C. P., 13th August 1912.

E. A. D'ABREU, F.z.s.

# No. XXIII.—NOTES ON THE SIZE AND BREEDING OF THE COMMON GREEN WHIPSNAKE (DRYOPHIS MYCTERIZANS).

Two common green whipsnakes were recently purchased from a snake-charmer, who said they came from Thana and Bandup (Salsette) respectively. Both were large specimens, the Thana one measuring  $6'-4\frac{1}{2}''$ , while the other was 5'-10''.

On 14th August the larger of the two specimens died in our museum and on being dissected was found to contain fifteen young ready for expulsion. Two days later the remaining specimen gave birth to eighteen young, one of which was born dead, having been unable to clear itself of the egg envelope. The remaining young sloughed on the second day after birth. They measured 13 inches.

Bombay, September 1912.

N. B. KINNEAR.

#### No. XXIV.—COBRA BREEDING AT PAREL.

During the past ten years many of the cobras (*Naia tripudians*) sent to the Bombay Bacteriological Laboratory have laid eggs while in captivity, but hitherto all attempts at hatching out young cobras have proved failures. Whether left with the mother, or kept apart from her, the eggs have always shrivelled up and no development of embryos took place. When kept in an incubator at blood-heat, the eggs became rotten in a few days, and when buried in dry sand they shrivelled up.

In 1905 a full grown krait (*Bungarus cæruleus*) and some half dozen eggs were dug up close to the Laboratory. Some of these eggs were kept in a box with the mother, and some were buried in the soil in which they were found. Both sets of eggs remained infertile.

In 1909, Major Liston, I.M.S., suggested that the cobra mother and her eggs should be placed in a glass case half full of sand, that the case should be darkened by winding cloth round it, and that the sand, and the cloth cover of the case be kept moist. Next day one egg was examined and a trace of embryo found. Unfortunately the mother died 9 days afterwards, and the eggs shrivelled up.

This year (1910) we had occasion to require a considerable number of cobras for experimental purposes, and four out of 21 laid eggs, and gave us the chance of experimenting further. Two of these cobras laid 21 and 22 eggs respectively, the other clutches were not counted as the eggs were glued together and mixed up with shreds of the mother's cuticle, and it was thought advisable to leave them alone. These latter batches all proved failures as far as hatching out young ones was concerned.

With regard to the period of the year when young cobras may be looked for, our experience is that the month of May is the usual time. Thus from 1st January to 31st May 1910 we received 24 cobras, of which 4 laid eggs; while after the 31st May 25 more cobras were received and none laid eggs.

The following table shows the date of receipt of cobras, and the laying of eggs:—

| Number. | Date of receipt of cobras. | Date on which cobra laid eggs. | Place from which received. |
|---------|----------------------------|--------------------------------|----------------------------|
| 28      | 11-1-10                    | 12-5-10                        | Khandwa.                   |
| 30      | 11-1-10                    | 14-5-10                        | 22                         |
| 39      | 20-4-10                    | 11-5-10                        | 22                         |
| 42      | 30-4-10                    | 9-5-10                         | ,,                         |
|         |                            |                                | 1                          |

The following is an account of the plan we employed with success in the case of the eggs of cobra No. 28:—

The eggs were laid in the tin biscuit box in which the cobra was kept on 12th May 1910. The eggs, 21 in number, were placed on the surface

of moist earth which four-fifths filled an ordinary garden flower pot. The eggs were then carefully covered with dry sifted earth to a depth of one inch, and the earth also slightly moistened. The pot was kept in a cool dark room. Next day we carefully removed the covering earth and found to our joy that the eggs were plump and fresh, looking though, of course, stained by the damp covering. The earth was replaced, and carefully sprinkled with water by old Benjamin, the snake man, who took quite a naturalist's interest in the proceedings. We had no idea of the incubation period of snakes' eggs, so sent Benjamin to enquire of some Bombay snakecharmers. He brought back news that 21 days was the recognised time. So on the 2nd of June, 22 days afterwards, we dug out one egg and opened it to see what progress had been made. The egg was quite plump and fresh looking, and contained a quantity of clear albumen, with a well formed embryo in one end of the shell. The small embryo snake was coiled up beside the yellow yolk, and with a small cord connecting it to a placenta attached to the shell. The embryo was white in colour, almost four inches long, and the heart could be seen distinctly pulsating. No scales could be made out on the skin, but the head, was large with two prominent eyes.

On the 23rd of June, i.e., on the 43rd day, we opened another egg, and found another living embryo in a further stage of development. It was some seven inches long, with well developed scales on the skin, and the heart could be seen beating vigorously.

The pot was watered daily as before, and was covered with wire netting as a precaution against the escape of the young should they happen to hatch out during the night. At length on the 18th of July, 67th day, a cobra head was noticed protruding, as far as the neck, from the egg shell. This specimen was removed from the flower pot and carefully washed in a basin. On enlarging the opening a little the embryo emerged with the placenta still attached.

On the following day others were found in a similar condition. They were left alone all night to see if they had strength to deliver themselves. Two had succeeded in this endeavour, but one of them being dead, it was thought advisable to render artificial aid to the others, and several of the little cobras lived for several weeks after. It was noted as a curious fact that all the young cobras had well developed spectacle marks on their hoods, although the mother was a black "cæca" from the Central Provinces, with no trace of a spectacle mark on the hood!

The new born cobras had a cutting chisel on the snout of the same shape and appearance as that described by Major Wall in the Society's Journal, Vol. XXI, page 693. Major Wall saw the specimens, but unfortunately the notes on the subject which he kindly jotted down have been mislaid owing to the transfer of one of us (Col.) W. B. Bannerman, I.M.S.) to Madras.

In all, 21 eggs were placed in the flower pot. Two were opened to see what progress the embryos had made; four were found shrivelled (on 4th June) and proved on dissection to be infertilised and quite solid. Of the 15 remaining eggs, 14 hatched out at full time, and one was dead in the egg but appeared fully developed.

W. B. BANNERMAN, I.M.S., Surgeon-General.

J. P. POCHA, LM. & s., Senior Assistant Surgeon.

Bombay Bacteriological Laboratory, Parel, 15th July 1912.

# No. XXV.—BREEDING OF THE COMMON GREEN VIPER (LACHESIS GRAMINEUS).

On 30th June a female Common Green Viper which was said to have come from Khandalla gave birth to fifteen young in our Museum. They sloughed first on 24th July. The brood vary considerably in colour, some being much darker than others and nearly all show the blackish markings on the back, though in the light coloured ones it is very faint. The mother belongs to the variety which has a yellow line along the side of the body, but in the young this line is hardly discernable. It has been found impossible to get the young snakes to feed naturally, though they have been tried with earth worms, young frogs, grasshoppers, young cockroaches and other insects. They have however been fed twice with raw meat and the nine which are still alive look well and are beginnin to grow.

Bombay, September 1912.

### No. XXVI.—SAW-SCALED VIPER (ECHIS CARINATA) AS A TREE SNAKE.

Some time ago a note appeared in the Journal stating that the phoorsa very rarely climbs trees. At the time I doubted the correctness of this as regards the habits of this snake in North Gujarat, as ten years ago I frequently found a snake, which I believed to be of this species, on cactus hedges and in bushes and small trees a few feet from the ground. I presumed however that I might possibly have been mistaken in my identification of the species, though I did not think it likely. I have now returned to the same part of the country and find that my original belief was correct. In confirmation I am sending you a specimen of *Echis crainata* which I found this week and killed in the outer branches of a

lime tree at a height of 4 feet from the ground. Echis is not a difficult snake to recognise if one knows its "points" but perhaps you will kindly confirm my identification.

A. H. E. MOSSE, CAPT., I. A.

PALANPUR, N. GUJARAT, 23rd July 1912.

[The specimen sent by Captain Mosse is certainly Echis carinata.—Eds.]

#### No. XXVII.—HABITAT OF ECHIS CARINATA.

It is generally supposed that the saw-scaled Viper (*Echis carinata*) is rarely seen at a height of 5,000 feet. Major Wall in his book "The Poisonous Terrestrial Snakes of our British Indian Dominions" writes of the *Echis*: "It is an inhabitant of the plains and becomes progressively scarcer at altitudes ranging up to 5,000 feet. 5,700 feet is the highest I know of."

It is of interest therefore to note that at Kacha Thana, a small outpost in the hills of the Chagai Tahsil of Baluchistan, at an altitude of 5,000 feet, the *Echis* is quite common. During the past three months I have obtained six specimens, all from the Kacha nullah, at heights ranging from 5,000 to 5,400 feet.

Unlike the Persian Horned Viper, another common snake in this locality, the *Echis* is apparently not timid in approaching human habitations. About a fortnight ago while the Officers of the Garrison were sitting in front of the Mess Bungalow before dinner, an *Echis* was observed quietly making its way under the chairs. It passed beneath the whole line of deck chairs and was unconcernedly heading for the verandah when I captured it.

Local Balochis call the *Echis* "landi mar" evidently in allusion to the brevity of its caudal appendage. It is also occasionally named "gwanden mar" or "little snake" in contradistinction to the "shakhwala mar" (*Pseudocerastes persicus*), an altogether bigger and stouter snake and the only other poisonous species common in this part of Baluchistan.

G. G. JOLLY, CAPT., I.M.S.

KACHA THANA, 2nd September 1912.

#### No. XXVIII.—"POISONOUS" LIZARDS IN INDIA.

With regard to "poisonous" lizards you may be interested to have one little piece of negative evidence. Last Saturday (17th) being Nag Panchami up here, some of the servants went round showing a number of snakes and a "gubera" (young Varanus). We were assured that this was deadly poisonous, but after it had been on show for about three hours—with a string tied round its middle—it apparently got annoyed and turned round and bit the man in his finger. The unfortunate man sucked

the wound and looked rather frightened and then went on showing his snakes; he is still alive and doing his regular work.

H. F. SAUNDERS.

THE FORT, GWALIOR, C. I., 26th August 1912.

[This subject was thrashed out in the early numbers of our Journal, Vols. III and IV (1888-9), but the belief is still apparently as strong as ever in Gujerat, Sind, Rajputana, Central India and Baluchistan that the young of the *Varanidæ*—otherwise known as Monitors or "Ghorpads," "gho-samps," also "Bis-cobras"—are poisonous.

It is difficult to trace whence this opinion has arisen. In Kaira, Gujerat, it is known as "Chandan-goli" and is "said to be as deadly as a cobra and able to spring ten paces" (A. Wood, I.C.S.).

Other lizards in India also bear an equally evil reputation, particularly *Euble-pharis hardwickii* and *E. macularius*, but so far as can be ascertained *no lizard in India is poisonous*.

According to Mr. E. E. Green "the Brahminy Lizard," the common skink, *Mabuia carinata*, holds a similar reputation in Ceylon. He mentions a case in which a lady was bitten by one of these lizards. The injured finger in a few hours' time became swollen and tender but by next day practically all the swelling and tenderness had disappeared.—EDS.]

### No. XXIX.—THE FOOD OF A BULL-FROG (RANA TIGRINA).

In Vol. XXI, No. 2 of our Journal, Mr. S. P. Agharkar states a few things about the diet of a bull-frog (*Rana tigrina*) and remarks at the end of his note that "further observations on this point by our members would yield interesting results." Taking advantage of this remark I put down a few observations on the subject.

On the 5th of September 1910 I dissected a freshly caught frog (Rana tigrina) before my B.A. students. On opening the animal, the very first thing, which struck me, was the unusual size of the stomach. I made an incision on the wall of the stomach and on carefully examining the contents I found to my surprise a big mole-cricket (Gryllotalpides), twenty maggots of a fly, a big beetle (Scarabæidæ), a small shell of a snail and some green vegetable product.

On another occasion, I had put a frog in the cage of a John's earth snake (*Eryx johni*) to serve the latter as its food. In the cage as much of the sand was spread as would be sufficient for the snake to hide itself. After 3 days when I saw that the snake would not go for the frog, I took out the latter and dissected it. On dissection it was found out that the stomach was tensely filled with sand. I cannot say definitely whether the frog had swallowed sand to get some nourishment from the small insects in the sand or for some other purpose.

BIOLOGICAL LABORATORY,

J. P. MULLAN, M.A.

St. XAVIER'S COLLEGE, BOMBAY, 16th August 1912.

#### No. XXX.—VITALITY OF A BUTTERFLY.

While watching a cluster of about thirty Papilio philozenus which were feeding on the flowers of a creeper, I noticed one of these butterflies had a large heavy pin driven through the thorax. It must at some time have been caught and pinned down, afterwards escaping. It was in very good condition and the pin did not seem to interfere in any way with its powers either of feeding or of flight, for when I tried to capture it by taking hold of the pin, it darted away and showed itself as strong on the wing as any other of its kind.

G. A. HASSELS-YATES, CAPT., R. G. A.

KHYRA GALI, MURREE HILLS, 11th July 1912.

### No. XXXI.—THE BED BUG (CIMEX ROTANDATUS) ON THE COMMON YELLOW BAT (SCOTOPHILUS KUHLI.)

Now that the responsibility of the Bed bug for "Kala azar" has been established, an observation I made in 1907 of the presence of the bug on two specimen of the Common Yellow Bat Scotophilus kuhli gains in importance. The bats were taken singly from holes in two cocoanut palms in a village near Tellicherry and were badly infested. Captain Patton, I. M. S., who kindly identified the bugs as Cimex rotandatus desired me to collect more bats of the species, but pressure of work of a different kind has left me little leisure to do it and I venture to publish this note in the hope that it will induce others interested to look for the bats and the bug on it.

I may mention what struck me as curious at the time that the bugs were on the bats themselves, rather an unusual habit for the insect. Perhaps the reason was that it was 7 A.M. when 1 caught them and the bugs starving over night had started just then to feed. The cocoanut trees were about 30 yards from human habitation. The holes on them could not be examined.

K. KUNHIKANNAN, M.A., F.E.S., Assistant Entomologist, Bangalore.

Bangalore, August 24th, 1912.

#### No. XXXII.-FLIES ON SNOW.

On the snow covered slope of a glacier in Kashmir at appoximately 15,000 I noticed that part of it, which I was ascending, was discoloured by what seemed to be a coarse, blackish dust, the snow elsewhere being clean and white. My eyes being fixed on this discoloured snow as I climbed, it suddenly dawned on me that the particles of 'dust' were in motion, jumping, and constantly shifting position. At first the thought occurred that I must be suffering from a severe 'go' of vertigo or mountain sickness,

but closer scrutiny revealed the fact that what I had taken to be dust was, in reality, a swarm of minute diptera. These tiny flies were thickly peppered over the snow for a space of 100 square yards or more, and apparently preferred to stay where they were or else were incapable of removing themselves by flight. How they got there, or into the predicament in which I found them, is difficult to conjecture, but if I might hazard a guess, I should say they had been wafted in a swarm, in a warm strata of air, from the valley beyond, and, suddenly meeting with the cold air above the glacier, collapsed and fell on the snow in a body.

KASHMIR, July 1912.

H. A. F. MAGRATH, LT.-COL.

#### No. XXXIII.—PRESERVATION OF GAME.

Some notes by Capt. Mosse on Mr. Hick's "40 years among the wild animals of India" have induced me to give a few details and make a few suggestions on the subject of game preservation.

Owing to the courtesy of a former Manager of the Court of Wards, I had, in 1911, the opportunity of shooting in one of the largest of the Zamindarys of the Central Provinces. My primary object was to secure a couple of good heads of that fast disappearing race—the C. P. Buffalc—and anything else, provided it did not interfere with my securing these.

The Zamindary has an area of something over 2,500 square miles and I had the opportunity of going over some 1,500 of this and in the localities where it would not be unreasonable to expect to see game fairly plentiful. If it had been during the cold weather that I went over this splendid piece of country, there might have been the argument—difficult to overcome—that one could not expect to find game universally plentiful over such a large area of, except for village sites and deserted village sites, uninterrupted jungle. I was however there during the months of April, May and June. At that time of year till the break of the rains, water is very scarce and there are frequently several miles between one patch of water and the other and if there were game about, their tracks would be found at the water. Although continually about before sunrise, I did not come across a single chital and only once a sambar and that was on the borders of Government forest whence it had come a few hundred yards to feed and where it returned at daybreak. There were several things which appeared to me to be conducive to this state of affairs.

#### (1) The Native licensed to have a gun.

In order to show how this man does the greatest amount of harm and the least amount of good: I should note that in this part of the country there is one harvest of rice, which is sewn at the commencement of the rains and reaped in September or October. Protection of crops is the excuse for a gun in many cases and a very legitimate excuse too, provided the use of the gun was limited to that. Shooting animals over crops gives both man and animal a sporting chance, anyhow in the estimation of the native and neither crops nor animals would be much the worse. The native however looks a bit further ahead and works out the simple problem that if there are no animals to shoot there will likewise be none to eat the crops. He, therefore, during the hot weather, when water is an absolute necessity and sport (for him) an absolute certainty, sits over the very limited numbers of water holes and makes use of his gun till there are no animals left to shoot. Now it appears to me that there are not insurmountable difficulties to get over and that a little local and if not sufficient, provincial legislation would make this state of affairs impossible. Let the protector of crops have his gun while his crops are in the ground and until they are reaped, which in most cases would be for four months-June, July, August and September. Let the native shikarry also have his gun for those four months as well and he will be able to pit his cunning against that of the unfortunate deer and the results of his labour will be sport and not slaughter.

#### (2) The village nets.

These nets, kept in every village inhabited by Mariahs, and in many other villages as well, are capable of catching any thing from a sun bird to a full grown Nilgai. It is probable that these are not on view in the same way when an official of the district is on tour, but in no case did they consider it necessary to put them away on my approach. I met a Mariah one day in the jungle and he explained their method of shikar with nets. Villages band together, bring out all their men and all their nets. After having arranged the nets in a run where animals pass, the jungle is beaten towards these and any flesh is good for the Mariah pot. The man told me that they had had a large beat a few days before, for miles around, but had not seen anything. It is not difficult to understand that game of all sorts under these circumstances must soon cease to exist. As far as I could ascertain the sale of flesh is not the object in these wilds, but the animals secured are divided with strict impartiality between those concerned in the beat. I was a witness of one of these partitions and the sport obtained was a jungle cat, a most unwholesome looking animal, but this was carefully divided up and put on leaves in a row. Nothing was wasted and the last of the flesh was being scraped off the cheek and carefully put aside for some one when I came up.

No doubt animal product is the property of these primitive jungle fellows, but their methods are those of extinction and if they are not restrained all animal life is bound to die out. The thriftless constructor is prevented from ruining the jungle at the expense of Government or the State and in his own interests the jungle man should be restrained from exterminating game on which he partly exists.

I also had occasion to see how birds fared at the hands of these ignorant

folk. Within a few miles of where I was one day camped, the pugs of a tiger had been seen in a dry water course in which there were two small pools of water where apparently the animal had drunk on the previous night. I intended to tie up in the water course and see if I could get the tiger. I went down in the afternoon and found that round the first pool branches of trees had been arranged to scare birds and prevent them from drinking there. At the second pool the same had been done and also a small hut of green boughs had been erected a few yards from the pool. In this case, however, a wet patch of sand had been left to entire thirsty birds on a sultry afternoon in the middle of the hot weather. Hidden just under the surface of the sand, was a jointed wooden frame working in the same way as a spring trap, with fine netting on either side of the frame. This frame was connected by a long cord to the hut in which the bird catcher and his son sat. By pulling the cord, any unfortunate bird up to the size of a peacock was secured the moment it put its feet on the enticing piece of wet sand. There is nothing to prevent the jungle man catching his birds in this manner and one might just as well talk to him of the evolution of the eroplane as attempt to reason with him concerning extermination. When I got up to the pool I asked to see what sport they had had and in the hands of an urchin of some 8 summers were the plucked remains of 3 unfortunate still-fluttering birds, one of which was the beautiful male Pitta brachyura. I put an end to their sufferings as speedily as possible. I felt it my duty, although I cannot flatter myself that it would have any lasting effect, to protest against the needless barbarity of plucking these unfortunate birds alive and after thoroughly explaining to the man my reasons, destroyed the trap. I sat up that evening and no tiger came, but the hen of this lovely thrush (Pitta brachyura) was hopping round picking up insects and with those dark patches like large tear drops looked as if she was mourning the cruel fate of her mate.

A plea for the Central Province buffalo.

I do not think any one will dispute the fact that this splendid animal is fast disappearing and sportsmen of former years would turn in their graves were they be acquainted with the conditions that now exist.

In conversation with a well known sportsman, a forest officer, some time ago, the subject of preservation of buffalo cropped up, and I remember him saying that it was very disheartening, as a stock of these animals may have been preserved and looked after for years only to be wiped out by some cattle disease which may attack them at any time. It appears to me now that this risk might be lessened and possibly entirely avoided the part of the country frequented by these animals consists of undulating plains of grass and scrub jungle and are the grazing grounds of thousands of cattle brought into the country from the Decean by "Banjaras" (a

wandering tribe) at the commencement of the hot weather and they remain till the break of the rains. There is not a corner of this vast area, where there is grazing, where these men and their herds do not penetrate. If cattle disease were introduced, it would more likely emanate from these cattle than from any other source. But these wandering tribes having paid their 2 annas a head (I think it is) for each animal are at liberty to wander at will and it is difficult to disassociate poaching, theft, or any other rascality from a member of a wandering tribe, although cattle-grazing may be his ostensible means of livelihood. There are parts of a jungle where buffalo will remain throughout the year, provided they are not rudely disturbed and there are parts which they never frequent or only pass through during the rains. Knowing these areas, surely it would be possible to close those they frequent to all grazing, and the areas would not be very large. This would give the buffalo a chance, his water would be left alone and the chance of him being killed off by cattle disease would be greatly diminished. I obtained one head of the C. P. buffalo a photo of which may be considered sufficiently interesting to reproduce in the Journal. I have no intention of visiting this part of the country again, but if what I have seen, and any

suggestion I have made would lead to preservation of game, especially of the buffalo, I shall not have written in vain.

ST. G. de CARTERET.

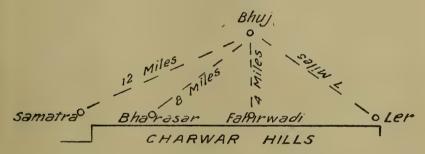

July 1912.

### No. XXXIV.—NOTES ON CUTCH AMMONITES.

П

In my last notes, on the Fakirwadi Belteram beds, I drew attention to the peculiar arrangement of the hills bordering the great Cutch fault. They fall into a string of circles, semicircles and curves so much so that one is sometimes inclined to think that there is not so much fault here as a steep dive of the North side of an anticline under the later beds. However in other places the fault theory seems more probable. Possibly the formation of the fault had a good deal to do with the circling of these hills.

This 'Circling' is not confined to the Fakirwadi beds.

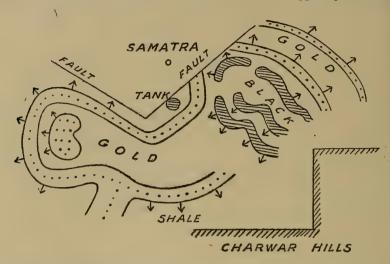

At each of the places named, Samatra, Bharasar, Fakirwadi and Ler I find the Ammonite ridges or hills turned in curves or circles, the North descent of the anticlines being often visible (perhaps only as a low broken off outcrop) dipping steep North and often clean gone, as if the curved hill had been shorn down across its middle by a fault.

Of Ler more later: of Fakirwadi I have written: of Bharasar this much at present: the outcrop here bends round at its East extremity in a most graceful curve: you might call it the end of a stadium. The South side dives under Charwar, the East dives down Eastwards, and the North side dives down to the North for a few hundred yards and then disappears. How far the Southerly exposure extends towards Samatra, I cannot say; I have followed it out for about  $1\frac{1}{2}$  miles, and it was still running Westward when I left it.

To-day I write of Samatra, which again has its circle or stadium. The shape of the Samatra outcrops of Ammonite beds is roughly this. A sort of 2 mile long stadium. Its beds dip quaquaversally, but I am not quite sure how far they extend to the South-East and South-West. All the

West side is a plain of golden yellow soil, except where a basalt intrusion has forced up the rock (and hardened it) into a biggish pile of hills.

From this mass of hills the yellow fields and slope away to the East, till crimson black slabs come sloping up from under the yellow fields and rise into high hills at the East end of the stadium, break off into very rough and tumbled ground and sink down again below a broadish yellow belt. Here too in one place are some hummocks of basalt, the intrusion of which is probably responsible for the upheave. At the South-East corner the hills rise up and join a projecting angle of the Charwar range: but I have not yet had time to study the junction point.

To the West and South except for a South-West extension for a long way not yet mapped the wet blanket of shale-coated with small broken red stone covers up the warm yellow beds, just as it does on the South side of the Fakirwadi beds: on the North side, the line of the fault is visible, hard cold coarse sandstone dipping South, i.e., against the Ammonite dip. To the East the yellow beds of Ammonite extend to some distance yet fully explored. I call the shale beds a wet blanket because you may hunt for hours in them and find nothing.\* Its deposition seems to have cut off all (shelly) life.

<sup>\*</sup>In a bit of coarse sandstone of the upper Jurassics lying apparently a fair height above the shale beds I have to-day found the relics of an Ammonite so perhaps Ammonites did struggle through the shale period: anyhow they must have done so to continue through into Cretaceountimes, unless as I sometimes think these masses of shale beds and upper jurassic sandstones are contemporary with the European cretaceous deposits. But there has been an intrusion of basalt not far off the spot, which may have carried up some of the Ammonite rocks through the overlying shale and sandstone left this waif here.

One peculiar feature of the ground is the curve which indents the North side. There are several low parallel wells—the outcrops of the harder Ammonite strata—running along the North edge; but they curve at right angles at this point: each of them—as do also the sandstone beds to the North. There was a bad kink in the fault here.

We must then suppose that at one time the whole stadium was a vast hill; all its centre has been eroded, and has probably become much more so in the last 31 years: anyhow a very low ridge is marked in the Trigometrical Survey Map which certainly doesn't deserve a contour line, now but then other hills deserve a contour line, which do not get it.

Basalt heaved up the West end: basalt heaved up the East end. Now the hills of the East end are of crimson-black rock, weathering on their inner faces into light yellow grit, while their broad slabby backs remain black and grim as contrasted with the golden yellow of the main stadium. They are of lower, earlier, deposit: and I presume Dr. Waagen refers to these when he writes of the Anceps beds of Samatra. I found two or three Anceps among them and several other Interrupti Perisphinctes, which I could not name. They also contain many biggish flat broad-trimmed Ammonites for which I can get no satisfactory name from the list of those supplied to Dr. Waagen.

The lowest beds visible in the lowest part of the hollow of the Eastern clump of hills seem to be of a dirty white sandstone—beds lying almost level—with, it seems, no fossils. Above them belemnite bearing rocks appear: these also contain very big Rhynchonellæ. At one spot on the outer edge of these black rocks there is a whole swarm of these big Rhynchonellæ. Embedded in the black rocks on the slabby side can be seen many big specimens, much worn and inextricable. One looked to be a long ribbed Stephanocéras. Another specimen was a big Aspidoceras (as far as I could judge). Its upper surface was worn almost flat and squat with the rock: I barely noticed it: but I did and I set to work carefully and long. As I removed the surrounding matter, it broke up. On unearthing a big outer fragment, I found strong straight even ribs, which from its shape and volution pointed to an Aspidoceras. It was 22 inches across and I much lamented its loss.

A big Rehmanni† was also found not far off. Above the black rock comes the golden yellow, which I consider to be athlete beds for in the lower parts of the deposit I found many athlete fragments. There were also large numbers of Perisphinetes rota many Per. dhosaensis, great numbers of fragments of Stephanoceras opis (at least I can see no other Stephanoceras in Waagen's book to which these fragments answer): unfortunately I found no specimen with inner whirls: Stephanoceras polyphemus, tumidum, and diadematum, Per. curvicosta, angigaster, and Indogermanus and

<sup>†</sup> Now in the B. N. H. S. Museum: a fine big fellow.

Harnoceras eairense and dynastes. One well preserved Echinolampas (discoides?) was found here too; if the identification hazarded by Mr. Stone is correct, this is a rarity in so low a bed.

In the hills on the west of the Stadium there is one corner in which good specimens of Harpoceras Dynastes abound. And another odd feature of these West hills is the great abundance of small Ammonites, evidently cut off by early death: perhaps the basalt rose and poisoned or heated the water while these beds were still forming, for these seem to be the highest of the ammonite beds here exposed. Their flat slabby backs slope down to the cold red stone beyond.

There are hundreds-probably thousands-of these immature examples exposed, though the majority are in fragments. I cannot be sure yet of any having their body chamber preserved; but there is no sign of any outer whorl having covered those now exposed. I promise myself and Mr. Stone an exciting time in examining these and guessing into what class of monster each would have grown.

And so this chapter of ancient life seems to begin in a jump with platelike Ammonites, Belemnites and big Rhynconella. Probably their ancestors lie crushed and powdered in the dirty-white rock of the lowest visible stratum. And they pass on through centuries of evolution into slightly varying forms, the old ones dying out and leaving descendants unlike themselves to start ever more widely differing branches. Suddenly while the waters are teeming with the life of these beautifully-shelled animals, there comes a bubbling up of hot or poisonous basalt. The waters get hot or poisonous and kill off all. The mud, till now flat and level, is heaved up into mounds and hills, and the whole mass is raised above water level into a small island.

One more point for notice: the Fakirwadi upper beds overlying the reefs with Samatra like species, contain many Perisphinctes, Oppeliæ and Phyllocersa: but the Samatra beds have not yet these upper layers: I have found none of the Perisphinctes so common to the upper Fakirwadi levels. (torquatus, Katrolensis, Pottingeri, &c.): possibly a few Oppeliæ in the Samatra upper beds, but so worn as perhaps to be Harpocersa: and one possible Phylloceras which refuses to budge from his compact rock-setting. So I think we may assume that these Samatra beds were clear of the water when the upper Fakirwadi beds were being laid down under water. But where did the water-line come? If it still washed the base of the hills sketched above, the Oppelia, Phylloceras and later Perisphinctes should be found under the cold red-stone shales round the edges of the raised island. This question must be solved by a close examination of the nullahs cutting through the cold red-stone shales; and this must wait a bit.

J. H. SMITH.

P. S.—The Nautilus and Ammonite specimens have been, as far as possible, identified by reference to Dr. Waagen's work on the Jurassic Cephalopoda of Cutch. (Pal. Indica Ser. IX. 4. vol. I. Pts. 1-4.). Several specimens discovered do not seem to tally with any given in Dr. Waagen's work: these are now awaiting identification.

Among the specimens from Samatra, as yet identified by Mr. F. H. Stone, are the following:—

| Belemnites grantianus <sup>1</sup> . | Stephanoceras tumidum <sup>3</sup> . |
|--------------------------------------|--------------------------------------|
| " gerardi.                           | " polyphemus.                        |
| " katrolensis².                      | Perisphinctes hians <sup>4</sup> .   |
| ,, sauvanausus.                      | rehmanni.                            |
| Amaltheus schaumburgi.               | curvicosta.                          |
| Harpoceras dynastes.                 | sparsiplicatus <sup>5</sup> .        |
| " lairense.                          | angygaster.                          |
| Peltoceras athleta.                  | dhosaensis.                          |
| " bidens.                            | omphalodes.                          |
|                                      | Also a Pleuromya.                    |

- Notes:—(1) Belemnites grantianus is mentioned in R. D. Oldham's Manual of the Geology of India, page 224, also in a footnote on same page as having been overlooked by Dr. Waagen in Jurrassic Cutch Pal., Indica Series IX.
  - (2) Bel. katrolensis being found in these beds shows that this species had its origin earlier than was known to former surveys.
  - (3) Steph. tumidum found in upper Athleta or Dhosavolite (the dividing line is not clear to me) shows a later extension in time than was formerly believed. Dr. Waagen allocated it to Macrocephalus beds only.
  - (4) Per. hians also seems to continue much later than was supposed. It was formerly assigned to Putchum beds (Bathonia). Here it is found in Callorian.
  - (5) Per. sparsiplicatus was only known in Katrol beds. There is no sign of Katrol beds here.

Mr. R. C. Burton, of the Geological Survey, Calcutta, has kindly examined the large number of small Ammonites referred to in the above article. He, however, reports that the specimens are too badly preserved for safe identification. They are limonite casts. However, he is inclined to believe that several which I had marked "Oppelia?" are real Oppelia, a point which is interesting, as Oppeliæ are so very rare (or absent) in the Samatra beds; and these small specimens found in the upper strata may have been the præcursors of a revival of the family. Large swarms existed in the Katrol seas.

\* \*

Mr. Stone has added the following to my Fakirwadi list:-

| Oppelia glabella.             | Perisphinctes orion. |
|-------------------------------|----------------------|
| " bicostata.                  | plicatilis.          |
| Harpoceras lunula.            | frequens.            |
| " ignobile.                   | chloroolithicus.     |
| ,, lairense.                  | Indogermanus,        |
| Peltoceras bidens.            | præcursor.           |
| " athleta.                    | euplocus.            |
| Aspidoceras iphiceroides.     | altiplicatus.        |
| Stephanoceras subtumnidum.    | rota.                |
| " diadematum.                 | sparsiplicatus,      |
| " semilæve.                   | spirorbis.           |
| Also Monttivaltic chariensis. | jooraensis.          |
|                               | leiocymon.           |
|                               | angygaster.          |
|                               |                      |

On the other hand, some of my indentifications (Vol. XXI. No. 2) must for the present be crossed out, viz:—Opp. orientalis, Harp. trilineatum and hecticum, Asp. divrsiforme and Wynnei, St. maya, macrocephalum, and fissum and Per. paramorphus.

The Fakirwadi beds extending about 250 yards horizontally thus contain Anceps, Athleta, Dhosa Oolite, Kuntkote (?), and Katrol beds.

The question naturally arises as to what formation the masses of shale and sandstone which overlie the Katrol beds (Tithonian) belong to? Dr. Waagen in the G. S. I. Records, Vol. IV., Pt. 4.. 1871, moots this problem Are they Cretaceous, and included in the 3,000 feet thick Umia beds of Mr. Vredenburg's Summary?

J. H. SMITH.

### NO. XXXV.—AMMONITES FROM CUTCH.

This sketch is meant to outline the probable history of the area during the Jurassic period and later, and to explain some of the points raised by the author in his paper (page ) entitled "Notes on the Cutch Ammonites."

In a Jurassic sea, the rocks containing the "Belteram" fossils were laid down. The sea was deep and little or no movement occurred in that area; Ammonitess, Belemnites and other deep-sea forms flourished and their remains were entombed where they lived.

A period of protracted earth movement began, the sea commenced to shoal slowly, allowing a deposit of fine, argillaceous material to collect over the "Belteram" beds. These conditions were probably not favourable to the existence of the *Ammonites*, &c., and they therefore moved into deeper

waters and to places on the deep-sea bottom where the conditions were more congenial to them and deserted the places where they formerly lived.

Occasionally, during this period of slow elevation, movement was arrested, the sea deepened and for a space, similar conditions to those that prevailed when the "Belteram" zone was being laid down, induced a few Ammonites, Belemnites, &c., to return and the remains of some of them are found where they died. The uplifting movement began afresh and the survivors fled when the argillaceous material began to envelop them again.

As the sea shallowed sufficiently to bring the area within the "Thalassia zone" of deposit, the sandstones of the Upper Charwar Age and of the Upper Jurassic Epoch were laid down over the Charwar shales.

The processes of sedimentation and movement kept pace till all the beds of Upper Jurassic age exposed within the area were laid down and then the crushing was accentuated and folding, along an axis parallel to the existing shore-line began, resulting in an anticlinal fold that was faulted along its crest when the movement became more intense.

About this time probably, the Charwar range came into being along the fault-line, as a faulted shale anticline forming a sea-cliff. Denudation removed this cliff backward, the sea encroached and planed down the shales, exposing the in-lier of "Belteram," which now formed part of the sea bottom.

Boulders were torn from these beds by the waves and dragged back and forth and left at various points of the sea bed, composed of the white Bhuj sandstones. The sea floor was finally elevated and the "Belteram" beds exposed in intimate contact with the white sandstones, along a line of fracture down throwing to Northward, that ran along the Belteram anticlinal.

As the movement became concentrated and localized along the fault, a series of domes were formed along the fold and gave rise to the line of circular hills referred to.

The fault often cuts along the crest of the fold and the fossiliferous, dark crimson, vanguard ridges, are probably the lowest beds exposed within the area.

The "Belteram" in-lier itself, forms an elongated dome, allowing the overlying Charwar shales to come in against the fault in the Nulla beyond the Barapur road.

The shales and "Belteram" beds exposed on the Bhuj side and beyond Dhonsar, are evidently the same series that form the Charwar range and "Belteram" hills, outcropping from below the Bhuj sandstones across the fault.

H. J. DAVIES, F.G.S.

CAMP LEDAUNG, 17th August 1912.

### NO. XXXVI.—THE TRINOMIAL SYSTEM OF NOMENCLATURE.

To open any discussion on "nomenclatorial questions" is, we know, treading on exceedingly delicate ground, but the subject has recently assumed such vast importance for all Naturalists that, it is felt that the time has now come, when it can no longer be shelved.

In a very remarkable book entitled "A Hand-List of British Birds" by Hartert, Jourdain, Ticehurst, and Witherby (published by Witherby and Co., London, 1912), a most thorough attempt has been made by the authors to settle, let us fervently hope once and for all, the vexed question of nomenclature. Each bird has, in this work, been assigned its correct scientific name in conformity with the Rules of the International Commission of Zoological Nomenclature. That this will now lead to uniformity can hardly, we think, be doubted. The uniformity, however, to be useful must be universal, and this universality can alone be arrived at by a strict adherence to the letter of the Law of Priority, against which there must be no appeal. It is only too notorious that the existing confusion has hitherto arisen by authors having systematically disregarded this important principle and individual tastes and fancies thus having been given free play, the same bird has been redescribed under different names. In the circumstances is it surprising when we see in text-books a mass of synonyms tagged on to each species?

That a large number of birds exhibit sub-species—by which term we mean not a "species in the making", but a "varietas geographica", a geographical race—will not be denied; and Ornithologists of the present day are fully alive to the great importance of the separation definitely of nearly allied forms of the same species. It is here that the Trinomial arrangement comes into play; and its use, not only helps us to speak with absolute precision of a particular race of birds, which have hitherto been binomially merged into other allied forms, but also helps to demonstrate scientifically the close relationship existing between geographical races of the same species.

The International Rules of Zoological Nomenclature clearly lay down how specific and sub-specific names shall, in the future, be accorded, and if universal uniformity is one of the desiderata, then there can no longer be any excuse for not adopting the principles everywhere. Henceforth (Article 2) the scientific designation of animals will be Uninomial for subgenera and all higher groups, Binomial for species, and Trinomial for subspecies. The Law of priority (Article 27) lays down that the oldest available name, even though it be inappropriate (Article 32), or "indicate characters contrary to those possessed by the animals in question" (Article 33) shall be adhered to. Doubtful cases, should any such arise, will have to be cleared by careful nomenclatures, with the help of the

International Commission, which discusses doubtful cases, and brings them up finally before the International Zoological Commission for decision. Unsightly tautonymy, such as *Apus apus apus*, or *Troglodytes troglodytes troglodytes*, is of no moment (Article 33).

As some doubts exist in regard to the use of trinomials for subspecies (geographical races), the authors of the "Hand-List" explain that when a species is divided into two or more races, or when two or more species are grouped as races of one species, then each of these races must have a trinomial appellation. It being impossible to say which is the oldest or parent form, the first named race of all those grouped under one species is, therefore, arbitrarily taken as the typical race, and its name becomes that of the species.

Applying these principles to a specific case, let us take that of the Raven as an example, and see how the revised nomenclature, in regard to the Indian birds, works out. The typical race of this Raven must, if it is to be distinguished from the Tibetan or Punjab birds, be designated Corvus Corax Corax, Linneus. As Hodgson was the first Naturalist to describe the Tibetan race under the binomial "Corvus tibetanus", then this, we take it, becomes, under the new Rules, Corvus corax tibetanus, Hodgson Similarly as regards the Punjab Raven. Hume originally described this as "Corvus lawrencii", and it would now become Corvus corax lawrencii, Hume, and so on for other races.

This "splitting" of species will doubtless be very distasteful to the old school of "lumpers", but its advantages in leading to a more exact knowledge of the distribution of birds can hardly be overestimated. We notice that the reformed system of nomenclature has been adopted by Messrs. Baxter and Rintoul in their Report on Scottish Ornithology for 1911, and it is apparently only a question of time now before it comes into general use. That we must now all fall into line and revise our labels is inevitable, but will it be too much to hope that our Society will take early steps, in consultation with experts in Europe, to help their field workers by having the binomial system of nomenclature used by Blanford in his Aves thoroughly overhauled, and by issuing a Hand-List of revised scientific names as required by the International Zoological Congress? In such a "List" the synonymy need be as brief as possible; references being simply given, as in the "Hand-List of British Birds", to the earliest names, and the typical locality for the bird described under that name.

P. T. L. DODSWORTH, F.Z.S., M.B.O.U.

SIMLA, S. W., 22nd August 1912.

[We understand that a revised list of the birds of India giving the various races is in preparation by one of our members at home.—Eds.]

### No. XXXVII.—CRUELTY TO WILD FOWL IN SIND.

With reference to the note on this subject by Captain C. H. Elliot in the last Journal, page 1083, and to the editorial note at the end, the following satisfactory letter has been received by the Society from Mr. A. D. Younghusband, C.S.I., I.C.S., Commissioner in Sind, dated the 27th June 1912:—

"I have the honour to refer to correspondence ending with your letter of the 12th February 1912, on the subject of cruelty to water fowl on the Manchur Lake, which has been very fully considered and discussed with the local officers.

2. I find that the question was taken up some years ago, resulting in the extension to the locality of the provisions of Section 62 of the Bombay District Police Act (IV of 1890) and of Section 3 of the Prevention of Cruelty to Animals Act (XI of 1890), which runs as follows:—

### Section 62, Bombay Act IV, of 1890.

62 (1) Whoever cruelly beats, goads, overworks, ill-treats or tortures, or causes or procures to be cruelly Punishment for Cruelty to animals.

Or tortured any animal, shall be punished with imprisonment which may extend to one month, or with

ed with imprisonment which may extend to one month, or wit fine which may extend to one hundred rupees, or with both.

(2) Jurisdiction in cases arising under this section shall not be exercised by a Magistrate of lower rank than the first class unless such Magistrate be specially invested with jurisdiction for that purpose by Government.

### Section 3, Act XI, of 1890.

Penalty for cruelty to animals in public places and for sale in such places of animals killed with unnecessary cruelty.

3. If any person in any street or in any other place whether open or closed, to which the public have access, or within sight of any person in any street

or in any such other place-

- (a) cruelly and unnecessarily beats, overdrives, overloads or otherwise ill-treats any animal, or
- (b) binds or carries any animal in such a manner or position as to subject the animal to unnecessary pain or suffering; or
- (c) offers, exposes or has in his possession for sale any live animal which is suffering pain by reason of mutilation, starvation or other ill-treatment, or any dead animal which he has reason to believe to have been killed in an unnecessarily cruel manner.

he shall be punished with fine which may extend to one hundred rupees, or with imprisonment for a term which may extend to three months, or with both.

- 3. Difficulties have however been experienced in the practical enforcement of these provisions of the law. It is one thing to be able to state that cruelty has been practised. It is another thing to produce such precise evidence against a particular individual of all the facts required to constitute a technical offence as will suffice for his conviction in a criminal court. Moreover there are certain doubtful points connected with the interpretation of the law. Such doubts can best be determined by the institution of test cases, and attention is being directed to the desirability of instituting them whenever opportunity arises.
- 4. It has now been arranged that in future the annual licenses granted for the capture of water fowl shall contain express conditions prohibiting all such cruel practices as that of breaking the birds' wings while alive. A proclamation is in course of issue to the public of the locality, warning them that such practices are illegal, and that the law will in future be strictly enforced against all persons resorting to them. And the local subordinate officials are being instructed to see that the warning is not disregarded.
- 5. The matter is one in which the co-operation of visiting sportsmen will be specially welcomed by the district authorities, and I shall be grateful if you canthelp, in enlisting such co-operation. It would be of the greatest assistance if any visitor under whose notice an act of cruelty may come would (1) make a full note at the time, of all relevant facts, including the names and descriptions of the offenders and of any witnesses, (2) give immediate information to the nearest Magistrate or police officer, (3) report by letter to the Collector of Larkana."

We are sure that all bird lovers and sportsmen will appreciate the action of the Commissioner in Sind in regard to the above matter, and it is hoped that all sportsmen will co-operate with the district authorities as suggested by Mr. Younghusband.

EDITORS OF THE JOURNAL.

### PROCEEDINGS

#### OF THE MEETING HELD ON 27TH JUNE 1912.

An "At Home" of the members of the Bombay Natural History Society took place on Thursday, the 27th June 1912, Dr. A. H. Deane presiding.

### NEW MEMBERS.

The election of the following 51 members since the last meeting was announced: -Capt. E. G. J. Byrne, Bombay; Mr. E. C. H. Condon, M.I.E., A.M.I.C.E., Bandra, Bombay; Rev. W. S. Sutherland, Kalimpong, Darjeeling; Mr. S. H. Covernton, Larkhana, Sind; Mr. M. T. Kennard, London; Mr. C. Saunders, Calcutta; Mr. J. B. Lloyd, Calcutta; Mr. W. G. Leys, Bahraich, Oudh; the Mess President, King's Liverpool Regiment, Lahore Cantonment; the Principal, Larkana Madrassatul-Islam, Larkana, Sind; the Honorary Secretary, Arthur Library, Castle Rock; Capt. E.D.F. Kelly, England; Mr. G. O. Allen, I.C.S., Mirzapur, U. P.; Capt. Gordon G. Jolly, I.M.S., Kacha, via Nushki, Baluchistan; Mr. G. T. Barlow, Jhansi, U. P.; Mr. Humphry Nevill, Phillaur, Punjab; Major L. L. Maxwell, London; Mr. G. N. Kingsford, C.E., Calcutta; Mr. C. F. Reeve, Nasrapur, Poona Dist.; Capt. L. A. Bethell, Dibrugarh, Assam; Dr. S. N. Gore, L.M. & S., Agra; Dr. J. M. O'Connell, Mannar, Ceylon; Rev. H. Fairbank, Ahmednagar; Mr. H. C. Robinson, Director of Museums, Kuala Lumpur. F.M.S.; Maharaj Kumar Shri Vijayarajji, Bhuj, Cutch; Mr. C. V. Birch, Bombay; Lt. E. B. Fawcett, Port Blair; Mr. John A. Wood, Kelantan, via Singapur; Mrs. Leslie James, Mandalay, Burma; Major B. E. M. Gordon, Manpur, via Mhow, C.I.; Mr. A. Oliver, Swatow, China; Rajkumar Hari Singh of Kashmir, Kashmir; Mr. C. G. Stewart, Tharrawaddy, Burma; Mr. Chas. Cook, Edinburgh; Mr. H. H. M. Spink, Ahmednagar; Capt. Norman Leslie, Darjeeling; Major H. F. Thuiller, R.E., Ahmednagar; Mr. L. Bishop, Hutti P. O., via Raichur, Deccan; Capt. E. J. C. MacDonald, I.M.S., Balek, Abor Hills, Assam; Mr. S. Hanhart, Bombay; Mr. Frank E. Rice, England; Mr. B. J. Gould, I.C.S., Gyantse, Tibet; Mr. Alister Forbes, Bombay; Mr. G. B. Lambert, I.C.S., Bijnor, U.P.; Mr. A. P. Kinloch, Pollibetta P.O., South Coorg; Mr. L. P. Hutchison, Gonda, Oudh; Mr. A. C. Tunstall, Calcutta; Miss Annie L. Skinner, Honorary Secretary and Treasurer, Natural History Society of Malaya, Kuala Lumpur, F.M.S.; Mr. J. C. Stodart, I.C.S., Pollachi, Coimbatore Dist.; Capt. W. Paget Tomlinson, Bangalore; and Mrs. T. W. Birkett.

The Honorary Secretary, Mr. W. S. Millard, acknowledged the following contributions to the Museum, since the last meeting:—

| Contribution.                                                                                                                                                  | Locality.                   | Donor,                                                              |

#### MAMMAL SURVEY.

### GRANT FROM BOMBAY GOVERNMENT.

The Secretary announced that he had just received a letter from the Government of Bombay intimating that Government had been pleased to sanction a special grant of Rs. 2,500 towards the funds for the Mammals Survey.

The survey is progressing satisfactorily. Mr. Crump is at present at Chanda, C. P., and Mr. Shortridge in Mysore.

The Superintendent, Victoria Gardens, Bombay, exhibited some plants of *Hæmanthus multiflorus* in flower.

The Secretary exhibited a plant of *Peristeria elata*, the 'Dove' Orchid, in flower.

An "At Home" of the members of the Bombay Natural History Society took place on Thursday, the 26th of September 1912, Mr. T. R. Bell, I.F.S., presiding.

The election of the following 37 members since the last meeting was announced:-Mr. G. M. McCleverty, Dehra Dun, U. P.; Mr. E. Lane, Koderma, P. O.; Mr. W. E. Kidner, R. E., Bombay; Mr. G. N. Frattini, Bangalore; Dr. E. H. Hankin, Agra; Mr. H. Gill, Kallini P. O., Cachar; Capt. W. G. Meale, I.A., Mount Abu; Mr. W. W. Phillips, I.C.S., Madras; The Librarian, Gauhati Club, Assam; Mr. Aga Shah Rookh Shah, Poona; Mr. Carl Meyer, Rangoon; Capt. C. H. Barbar, I.M.S., Banda, U. P.; Dr. A. D. Cunnyngham Perdriau, Narsinghpur, C. P.; The Mess Secretary, R. A. Mess, Meerut; Major H. N. Holden, Jaipur, Rajputana; Mr. B. L. Clarke, Quetta; the Honorary Secretary, R. A. Mess, Cambellpore; Major James Davidson, I.M.S., D.S.O., Dehra Dun, U. P.; Mr. E. D. Knowles, Purulia, B. N. Ry.; Mr. T. R. Rearden, England; Capt. T. L. Bomford, I.M.S., Calcutta; The Mess President, The Border Regiment, Maymyo; Mr. E. H. P. Jolly, I.C.S., Jalgaum; Mr. E. Ferry, Benares; Mr. E. L. Mahon, Pollibetta, South Coorg; The Principal, Madras Forest College, Coimbatore; Major A. D. Kirby, R.F.A., Allahabad; Mr. H. Jouquet, Dehra Dun, U.P.; Mr. F. C. Chamier, I.C.S., Mirzapur; Mr. E. A. Macnee, Jubbulpore, C. P.; Mr. T. J. Tasker, I.C.S., Hospet, Bellary; Mr. S. H. Harman, Tavoy, L. Burma; Mr. J. W. Bradly, Katha, Burma; Mr. V. A. Mackinnon, Mussoorie, U. P.; Mr. Donald Fraser, Bombay; Mr. B. S. Hickey, Tateriah P. O., Champarum and Mr. A. W. Botham, I.C.S., Shillong.

## 1362 JOURNAL, BOMBAY NATURAL HIST. SOCIETY, Vol. XXI.

The Honorary Secretary, Mr. W. S. Millard, acknowledged the following contributions to the Museum, since the last meeting:—

| 1-                                                                                                                                  | ,                                |                                                  |

### MAMMAL SURVEY.

The Secretary said since the last meeting Mr. Crump had sent in 227 specimens from Chanda, C. P., and Mr. Shortridge 106 specimens from Shimoga and 331 from Vijayanagar (Humpi), Bellary District. Mr. Crump was now in Kathiawar collecting and Mr. Shortridge at Kolar, E. Mysore, from whence he proceeds to Coorg and the Malabar Coast. In regard to finances, the Government of India had kindly responded to the Society's appeal by giving them Rs. 7,500, which was very acceptable but would unfortunately not permit the Society to bring out a third collector, a very desirable course if the Survey was not to drag on for the next five years.

#### EXHIBITS.

Mr. Kinnear exhibited the specimen of mammals which had been named and returned by the British Museum.

The Secretary exhibited the following flowering plants new to Bombay:—
Mussænda erythrophylla from Central Africa with bright crimson bracts (in contrast to the white bracts of the indigenous M. frondosa), Solanum pensile with violet and yellow flowers and Odontodenia harrisi with large pale yellow flowers and a salmon centre.

### MIMICRY IN SILK-WORM MOTHS.

(With Plates I, II and III).

The phenomenon of Mimicry, as presented by Lepidoptera, affords a most fascinating study to those who go about the world with their eyes openeven though they may not happen to be students of entomology. For instance, what beginner at collecting has not been struck by the startling resemblance of the female of Hypolinnas misippus (Linn.), to the common Danais chrysippus (Linn.)? or by that of the moth Epicopia rolydora (Westw.) to the Papilios of the Philoxenus group?—just to mention two very self-evident instances. What is the meaning of it? and why should  $\tilde{D}$ . chrysippus be such an exceedingly common butterfly? are questions which suggest themselves to us at once. These are phenomena which are presented to us, and it is "up to" us to endeavour to account for them in some reasonable manner, and not to pass the problems by as insoluble. In endeavouring to account for them, however, one fundamental rule must not be lost sight of, which is that the imitator and it's model must be or must recently have been inhabitants of the same locality, otherwise the whole theory of mimicry falls to the ground. As it happens, the solution of the apparent enigma referred to above is a simple one: the sub-family Danainæ to which D. chrysippus belongs have, as we all know, acquired the faculty of being distasteful to the many insectivorous birds and reptiles which prey upon, butterflies and moths, and so enjoy immunity from their attacks, and are consequently, numerous in individuals; and further, some of those forms, which do not possess this faculty, have gradually become developed in imitation of their more fortunate comrades, in accordance with the Darwinian Law of the survival of the fittest. The immunity of these specialized forms has probably been acquired as follows:—the larvæ of many of them are known to feed on Aristolochia indica, Gomphocarpus fruticosus and other Asclepiad plants which, when cut, exude a white milky substance which is exceedingly bitter to the taste, and the inference is that this quality is transmitted to the imagines and renders them distasteful. The Philoxenus group of Papilio is also protected by possessing, as imagines, a disgustingly rank odour, somewhat resembling musk, which is so strong and enduring that it remains even after the death of the insect.

Still the theory of protective imitation is a thorny subject to tackle, and it is with considerable diffidence that I write this paper dealing with another forms of mimicry as exemplified by forms of the family Saturniidæ (or silkworm moths). Any observer who has studied the family must have been struck by the faithful representation of a snake's head, which appears on both sides of the apex of the forewing in the various forms of the genus of the forewing of these forms appears to have been developed in imitation of the head of some snake: this phenomenon is apparent at once to anyone who places a piece of paper over a specimen in the cabinet, so as to cover up the whole insect from view except the apical half of the forewing.

I have figured the apices of the forewing of seven forms of Saturniadæ in my collection, which exhibit this character with greater or less fidelity, the two most striking representations being undoubtedly Attacus atlas and Attacus edwardsi, the former of which exhibits the snake's head in profile and the latter gives a view of the head from above, showing both eyes: the remaining forms though, perhaps, not so striking, give, nevertheless, an accurate delineation of a serpent's head, and point to general tendency towards snake mimicry in this family in forms from the Æthiopian and Nearctic regions as well as the Oriental.

It may be objected that the colours of these moths are very different from those of the cobra and other snakes, but allowance should be made for the moths resting under the shade of leaves, as they would often be, during the sunny hours of the day, when the colours would not show up so brightly. In such circumstances, well marked colouration would be necessary to bring out the details when in deep shadow, and even the apex of the forewing of such a brightly coloured moth as Loepa katinka (Westw.) might be mistaken for the head of one of the smaller bright green snakes. In any case, the phenomenon is a most remarkable one, and I have not read as yet of any reasonable explanation of it; that there is a reason for it is as great a certainty as that there is a reason for the existence of everything in nature, in the economy of which all forms of life work out their allotted duties. Let us try, then, to see how we may reasonably account for it.

Being of large size, these moths are conspicuous objects, when resting, and some protection is necessary for the continuation of the species. There are in India 213 species of snakes of which some 33 are poisonous: the food of many of them consists of rats, mice and small birds,—a percentage of which are insectivorous: the toll of birds taken by these reptiles must be very considerable, and is said to be obtained by the exercise of a mysterious power termed 'fascination,' the victim being held, as it were, by the gaze of it's destroyer, and compelled to remain in the same spot until the serpent can approach sufficiently near to seize it. It is clear, therefore, that an insectivorous bird in pursuit of a moth amongst the leaves of a tree would be quickly brought to a standstill by the appearance of a snake's head just as it was about to seize it's prey.

Now an Atlas moth resting amongst the leaves of a tree (as shown in Plate No. I.), with the apices of the forewing projecting and giving the appearance of a snake's head, would, in my opinion, have a good chance of escape from any insectivorous bird, which suddenly came across it; and as the upper and underside of the wings representing the reptile are coloured in a similar manner, the result would be the same on whichever side it was

approached.

Such appears to me to be the most likely explanation of the phenomenon.

Some remarks in detail on the forms figured may now be given.

Fig. 1.—Attacus atlas Linn—In this form a side view or profile of the snake's head is seen. The eye is represented by the black subapical spot, and the mouth by the crimson streak below it, while the dark markings with whitish edges and diaphanous spot in the centre of the wing would

serve to represent the "hood" and "spectacles" of a cobra.

Fig. 2.—Attacus edwardsi White.—This form gives the most startling and sinister representation of a Serpent's head of any of the forms figured. The aspect presented is that which would appear to an observer looking down on it from above; the violet subapical patch would represent the shining surface of the top of the snake's head; the small black subcostal apical spot is the left eye, and the somewhat elongated oval black spot between veins 6 and 7 the right eye, while the mouth and lips are shown by the submarginal and marginal lines; as in fig. 1 the central markings serve to represent the "hood" and "spectacles."

Fig. 3.—Attacus mithymna (Westw).—An African form representing a smaller species of snake viewed from above; the various details are well brought out in this form: central markings present, and give a fair representation of "hood" and "spectacles" of Naja haje, the African

cobra.

Fig. 4.—Attacus cynthia, (Drury)—A form very similar to the last, but much lighter in colouration; snake's eye and mouth well delineated. This

Sketch of Attacus atlas resting on the branch of a tree, showing the protection obtained by the apices of forewings resembling serpents' heads.

form is curious in that, while the outlines indicate unmistakably a snake's head, the colouration does not appear to have been modified to an equal extent. Inhabits the Nearctic as well as the Oriental region.

Fig. 5.—Samia cecropia (Linn.).—An American form showing a similar

aspect of a snake's head to the two last; both eyes are represented.

Fig. 6.—Saturnia simla (Westw.).—This form represents the snake's head as it would appear to an observer somewhat below it. Subcostal black spot representing eye, and pale subapical patch showing part of the snake's head above the line of the mouth. An interesting form as the hind wings appear to be somewhat modified, to represent an owl's head in certain positions. (Plate No. II).

Fig. 7.—Loepa katinka (Westw.).—This form is interesting in that it shows a marked tendency to snake imitation, even in a form in which the specific colouration does not lend itself to mimicry of this kind. Yet here we have the usual violet subapical patch referred to above, with a more or less developed black spot between veins 6 and 7, and the other eye in-

dicated by a minute subapical costal spot.

It is somewhat difficult to imagine surroundings in which this form with its unusually vivid colouration could be mistaken for a snake, unless, when resting among similarly coloured leaves in deep shadow, it may resemble

one of the smaller bright green snakes.

Another remarkable character in this family is the diaphanous spot in the centre of each wing: in the hindwing these are, in many forms, much enlarged and developed into conspicuous eye-like spots. These may be intended to afford protection by presenting the appearance of an owl's head when the moth is at rest amongst the leaves of a tree as suggested. (Plate No. II.). These spots are most beautifully developed in this direction on the hind wings of Telea polyphemus, Cramer, an American form. Of course, an owl's head would have an equally deterrent effect as that of a snake on a small insectivorous bird.

J. M. FAWCETT, Col., (late 5th Lancers).
